

Motivation

Election poll reporting

What's the status quo?

Typical election poll reporting:

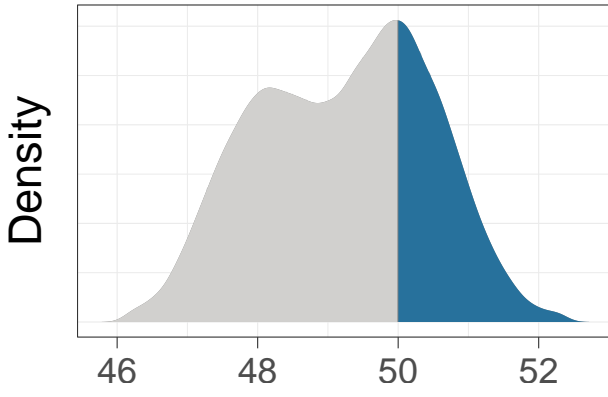

- is based on observed mean voter shares
- sets the focus on individual party achievements
- imparts sample uncertainty only insufficiently

Typical headline:

"The two parties jointly obtain 48% of all votes."

What do we propose?

Proposed type of reporting:

- focuses on specific events (e.g. potential majorities)
- naturally imparts sample uncertainty using probabilities
- prevents misunderstandings by using this holistic approach

Proposed headline:

"The two parties have a probability of 32% to jointly obtain a majority."

Real-world Example

Reporting on Union and FDP to jointly obtain a majority before the German federal election 2013

Last pre-election opinion poll: Source: Forsa, 20.09.2013

Union	SPD	Greens	FDP	The Left	AfD	Others
40%	26%	10%	5%	9%	4%	6%

After redistribution of party votes <5% (i.e. the minimum vote share to enter the German parliament) Union-FDP jointly obtain exactly 50%.

Media headline:

"Union-FDP loses its majority"

Source: FAZ.net (2017). Umfrage zur Bundestagswahl: Schwarz-Gelb verliert die Mehrheit. <http://archive.is/SuXVt>. Accessed 26 April 2018.

Flaws of this type of reporting:

- Misleading conclusions are drawn
A mean share of 50% only means that it's slightly more probable to miss a majority
- Sample uncertainty is ignored
E.g., with a mean voter share of 5%, FDP will only enter the parliament with ≈50%
- Redistribution of votes is ignored
FAZ.net bases the conclusion on the observed voter share and not on the redistributed 50% share

Foundations of KOALA-based reporting of POEs:

- Use event **probabilities** instead of voter shares
Probabilities comprise sample uncertainty in a natural way and are less at risk to be misinterpreted
- Use **event** probabilities instead of voter shares
Focusing on the main events allows the reader to easily grasp the relevant information

KOALA headline:

"Union-FDP gains seat majority with 26%, FDP passes into parliament with 51%*"

* If the election was held today

Methods

Estimating POEs

- Multinomial-Dirichlet model** for the true party shares θ_p (Gelman et al., 2013):
$$(\theta_1, \dots, \theta_P)^T \sim \text{Dirichlet}(\alpha_1, \dots, \alpha_P), \text{ with } \alpha_1 = \dots = \alpha_P = \frac{1}{2}$$
- Given one survey, we obtain a **Dirichlet posterior** with $\alpha_p = x_p + \frac{1}{2}$ for each party $p = 1, \dots, P$ and its observed vote count x_p .
- Using **Monte Carlo simulations** of election outcomes, we obtain specific POEs by calculating the events relative frequency of occurrence.

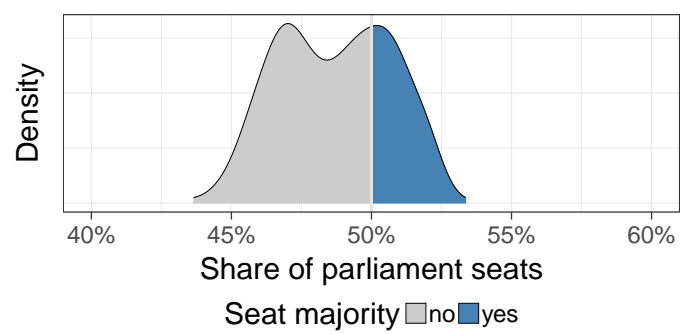

Pooling multiple polls

We aggregate the latest polls within a specific time window (e.g. 14 days) to reduce sample uncertainty. We adjust the uncertainty of the multinomially distributed summed number of votes per party by using an **effective sample size** (Hanley et al., 2003).

- As polls from different polling agencies are correlated, **party-specific correlations** were estimated based on 20 surveys of polling agencies Emnid and Forsa, using
$$\text{Cov}(X_{Ap}, X_{Bp}) = \frac{1}{2} \cdot (\text{Var}(X_{Ap}) + \text{Var}(X_{Bp}) - \text{Var}(X_{Ap} - X_{Bp})),$$
with
 - X_{Ap}, X_{Bp} the observed vote counts for party p in surveys A and B ,
 - $\text{Var}(X_{Ap}), \text{Var}(X_{Bp})$ the theoretical variances of binomial distributions,
 - $\text{Var}(X_{Ap} - X_{Bp})$ estimated from the party share differences.For simplicity, we set the correlation to a fixed value of 0.5.
- The **effective sample size** n_{eff} is then defined as the ratio between the estimated variance for the pooled sample and the theoretical variance for a sample of size one:
$$n_{\text{eff}} = \frac{\text{Var}(\text{pooled})}{\text{Var}(\text{sample of size one})}$$

Visualization & Implementation

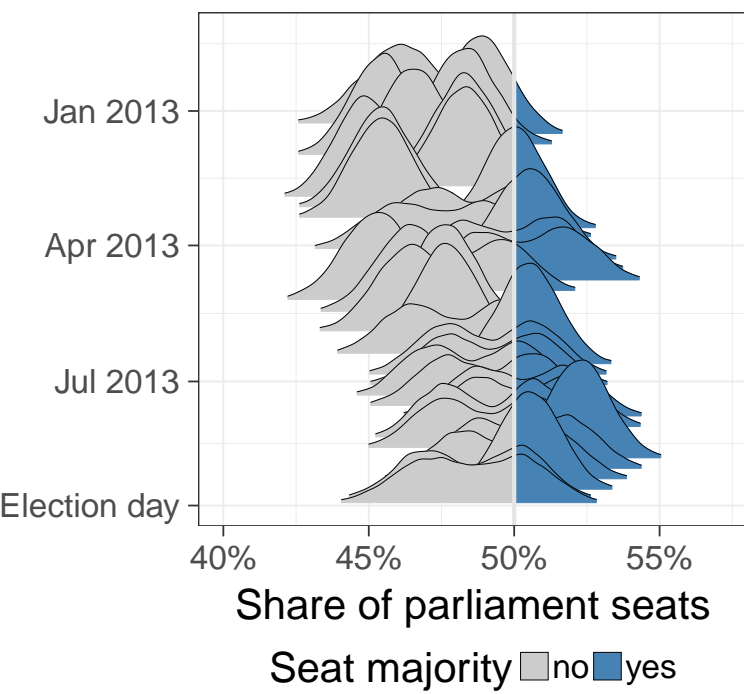

Selected visualizations

Density plots are used to **visualize POEs**, highlighting the area associated with simulations where the event of interest occurred. Furthermore, such plots also show

- the uncertainty underlying the event of interest
- the range of possible outcomes

in a natural and intuitive way.

Ridgeline plots (Wilke, 2017) are used to depict the **development of POEs**, again visualizing the uncertainty underlying the event of interest in a natural way.

Implementation

koala.stat.uni-muenchen.de

@KOALA.LMU

The **R package coalitions** (Bender and Bauer, 2018) includes all methods and allows for their application to any multi-party electoral system.

Our **dedicated website and Twitter channel** makes current POEs for selected elections accessible to the general public.
